Document Control

The following table provides essential metadata and configuration details for this Quality Assurance Testing Documentation.

Field	Detail
System Under Test (SUT)	UMHackathon 2026 — StockWise AI Inventory Optimizer
Team Repo URL	https://github.com/teohweibin/Team_Rojak.git
Project Board URL	https://yeesyuen647.atlassian.net/jira/software/projects/UT/boards/2?atlOrigin=eyJpIjoiYzVmMzczYjY1MmYwNDVmNGE1MTJmZGY1ZmVkZWYxOWMiLCJwIjoiaiJ9
Live Deployment URL (optional for preliminary round)	https://c1ye938tnkg0-deploy.space.z.ai/

Objective:

The primary objective of this Quality Assurance and Testing Document is to ensure that StockWise operates reliably and accurately across all core functionalities, including inventory management, sales tracking, exchange rate updates, and market news integration. The testing process validates that the system can correctly handle structured and unstructured data, process user inputs, and maintain consistent data flow between the frontend, backend, and database components within the application.

In addition, this document aims to verify the effectiveness of StockWise's AI-driven decision intelligence by ensuring that Z.AI's GLM generates context-aware, logical, and actionable recommendations. The system will be tested under various scenarios and edge cases to confirm robustness, proper error handling, and acceptable performance, ensuring that users receive reliable insights that support informed inventory and procurement decisions.

PRELIMINARY ROUND (Test Strategy & Planning)

1. Scope & Requirements Traceability

This section ensures that all testing activities are directly aligned with the core functional requirements of StockWise through a Requirement Traceability Matrix (RTM). It verifies that each implemented feature is adequately tested to prevent defects, ensure system reliability, and avoid unintended feature scope expansion. The testing scope focuses on validating both system functionalities and AI-driven decision outputs to ensure that the platform delivers accurate, actionable, and consistent results.

1.1 In-Scope Core Features

- **Inventory Management:** Managing stock levels, updating inventory quantities, and monitoring product status.
- **Product & Supplier Management:** Creating, updating, and managing product and supplier data, including pricing, supplier details, and currency information.
- **Sales Velocity Tracking:** Recording sales transactions, calculating sales trends, and visualizing revenue data.
- **Exchange Rate Management:** Tracking and updating currency exchange rates (USD/MYR, EUR/MYR, CNY/MYR) for procurement decision support.
- **Market News Integration:** Displaying curated market news and incorporating unstructured data into the AI analysis pipeline.
- **AI Recommendation Engine:** Generating AI-powered inventory and procurement recommendations using Z.AI's GLM, including reasoning explanations, priority levels, and estimated financial impact.
- **Strategy Validation:** Evaluating procurement strategies (conservative, balanced, aggressive) and comparing trade-offs across different scenarios.

1.2 Out-of-Scope

- **Real-Time News Scraping:** The system uses a curated static news feed instead of live data integration.
- **User Authentication & Role Management:** Multi-user login, access control, and role-based permissions are not included in the MVP.
- **Automated Purchase Order Generation:** The system provides recommendations only; execution of procurement actions is manual.
- **External System Integration:** No integration with ERP, accounting, or POS systems.
- **Mobile Native Applications:** The system is limited to a web-based interface and does not include native mobile apps.

2. Risk Assessment & Mitigation Strategy

This section identifies potential technical risks associated with the StockWise AI Inventory Optimizer, assesses their likelihood and severity, and defines mitigation strategies and corresponding testing approaches. The risk assessment follows a quantitative scoring methodology to prioritize testing efforts.

2.1 Risk Assessment Table

Technical Risk	Likelihood (1–5)	Severity (1–5)	Risk Score (L×S)	Mitigation Strategy	Testing Approach
AI generates incorrect or misleading recommendations	3	5	15 (High)	Include reasoning chain and source references for validation. Require user verification before action.	Provide conflicting or edge-case data inputs and validate if AI output remains logical and consistent.
GLM API failure or timeout	3	4	12 (High)	Implement timeout handling and fallback response (e.g., error message or retry mechanism).	Simulate API failure or delay and observe system behavior and fallback handling.
Invalid or malformed AI JSON response	3	4	12 (High)	Add response validation and parsing safeguards; ignore invalid entries and log errors.	Inject malformed JSON responses and verify system stability and error handling.
Incorrect or outdated exchange rate data	3	4	12 (High)	Allow manual updates and display the last updated timestamp for transparency.	Input outdated or incorrect rates and evaluate impact on recommendations.
Data inconsistency between modules (inventory, sales, supplier)	2	4	8 (Medium)	Enforce data validation rules and centralized data handling in the backend.	Perform CRUD operations across modules and verify consistency in the database.
Missing or insufficient input data for AI analysis	3	3	9 (Medium)	Implement input validation and minimum data requirements before triggering AI.	Attempt to generate recommendations with incomplete data and observe system response.
SQLite database limitations under	2	3	6 (Medium)	Use SQLite for MVP with a clear	Simulate multiple requests and

concurrent access				scalability plan to migrate to PostgreSQL if needed.	monitor database performance.
News data not relevant or outdated	3	3	9 (Medium)	Use curated and recent news; allow periodic updates before demo.	Test with irrelevant news and evaluate AI recommendation quality.

2.2 Risk Assessment Scoring Criteria

Likelihood (1–5)

Score	Description
1	Rare
2	Unlikely
3	Possible
4	Likely
5	Almost Certain

Severity (1–5)

Score	Description
1	Negligible
2	Minor
3	Moderate
4	Major
5	Critical Failure

2.3 Risk Level Reference

Risk Score = Likelihood × Severity

Risk Score	Risk Level	Recommended Action
1 – 5	Low	Monitor only. Acceptable risks.
6 – 10	Medium	Mitigate + Testing
11 – 15	High	Strong mitigation + thorough testing
16 – 25	Critical	Highest priority, extensive testing

3. Test Environment & Execution Strategy

This section describes the testing environment, execution strategies for each test type, and the data management approach used throughout the QA process.

3.1 Unit Test

Attribute	Detail
Scope	Individual API route handlers (POST /api/recommendations/generate, GET /api/inventory, etc.), utility functions (exchange rate calculations, inventory status threshold logic, sales velocity computations, data formatting helpers).
Execution Method	Manual testing via curl commands and Postman collections during active development. Each API endpoint tested independently with predefined request payloads and expected response schemas.
Isolation Strategy	Mock database populated with controlled test data via Prisma seed script. Test data includes known product configurations, predetermined sales figures, and fixed exchange rates to ensure deterministic test outcomes.
Pass Criteria	Correct HTTP status codes (200 for success, 400 for validation errors, 500 for server errors). Valid JSON response structures matching documented API contracts. All required fields present and correctly typed.

3.2 Integration Test

Attribute	Detail
Scope	Full-stack integration chain: frontend UI components → Next.js API routes → Prisma ORM → SQLite database. Covers all in-scope core features tested end-to-end through the browser interface.
Execution Method	After each page/component is developed, execute a full end-to-end test in the browser. Verify data flows from user interaction through the API layer to database and back to the UI.
Workflow	Real database calls using the Prisma client. Real AI API calls to Z AI GLM for critical paths (recommendations generation, strategy simulation). Mocked AI responses used only for UI development before AI integration is complete.

Pass Criteria	Data flows correctly through the entire chain. UI updates reflect database changes within 2 seconds. Error states display appropriate messages to the user. No silent failures.

3.3 Test Environment (CI/CD Practice)

Environment Attribute	Configuration
Primary Testing	Local development machine running Node.js 18+ with Next.js 16 development server.
Database	SQLite file-based database located in the project directory. Fresh database created for each test session using Prisma migrate reset.
AI Model	Z AI GLM accessed via ILMU API. API keys stored in environment variables (never committed to version control).
Browser Testing	Google Chrome on the development machine. DevTools Network tab used for API response inspection.
CI/CD Pipeline	No automated CI/CD pipeline configured for MVP. All testing performed manually.
Production Build	Tested via standalone server (next start) after successful production build (next build). Verifies that all features work in optimized production mode.
Version Control	Git repository with feature branches. Testing performed on feature branches before merge to main.

3.4 Regression Testing & Pass/Fail Rules

Regression testing is conducted after each significant code change to ensure that existing functionality has not been inadvertently broken.

- **Scope:** All 5 in-scope features are re-tested after any code modification, including dependency updates, refactoring, bug fixes, or new feature additions.
- **Pass/Fail Criteria:** Actual system behavior must match documented expected results for all test cases. Any deviation is logged as a regression defect with severity classification.
- **Defect Logging:** Failures are documented with test case ID, steps to reproduce, expected vs. actual results, and severity. Critical regressions must be fixed before proceeding with new development.
- **Frequency:** After every code commit that touches API routes, database schema, utility functions, or core UI components.

3.5 Test Data Strategy

A comprehensive test data strategy ensures consistent and repeatable testing across all sessions.

Aspect	Detail
Manual Seed Data	Prisma seed script (seed.ts) creates: 7 products across diverse categories (electronics, food, medical supplies, stationery), 4 suppliers with varied attributes, 30+ days of historical sales data with realistic daily variations, 3 exchange rates (USD, EUR, GBP to MYR), 3 pre-seeded AI recommendations for UI preview testing.
Automated Seeding	Prisma seed.ts executed via 'npx prisma db seed' before each test session. Database is reset (prisma migrate reset) to ensure clean state. Ensures deterministic starting conditions for all tests.
Edge Case Data	Additional manual test data created for boundary testing: products with zero inventory, products with very high inventory (>1000 units), suppliers with no associated products, dates with no sales records, exchange rate edge cases (very low, very high rates).
Data Cleanup	Full database reset between test sessions. No residual data from previous tests. Ensures each test session starts from a known, clean state.

3.6 Passing Rate Threshold

The following thresholds define the minimum quality gates for the project:

- **Overall Pass Rate:** Minimum 80% of all test cases must pass for the project to be considered ready for submission. This includes all test types (unit, integration, regression).
- **Critical Test Pass Rate:** 100% pass rate required for critical test cases, specifically: AI recommendations generation (valid JSON, complete schema), inventory status calculation (correct threshold classification), and mathematical simulation accuracy.
- **Non-Critical Flexibility:** Non-critical features (e.g., chart rendering edge cases, UI animation timing) may have a lower pass threshold but any failure must be documented with impact assessment.

4. CI/CD Release Thresholds & Automation Gates

This section defines the quantitative thresholds and quality gates that must be met before the application can proceed through the build, test, and deployment pipeline. While the MVP does not have a fully automated CI/CD pipeline, these thresholds serve as manual checkpoints during the development process.

4.1 Integration Thresholds (Merging to Main)

The following checks must all pass before the application can proceed to deployment testing:

Checks	Requirements	Project	Pass/Failed
Build	Zero Build Error — 'next build' must complete with exit code 0 and no TypeScript compilation errors.	next build completes successfully with zero errors and zero warnings.	Passed
ESLint	Zero Linting Error — 'next lint' must report zero errors. Warnings are acceptable but should be reviewed.	ESLint reports zero errors across all source files.	Passed
API Health	All Endpoints Return 200 — Every documented API endpoint must respond with HTTP 200 (or appropriate status code) to valid requests.	All API endpoints return expected status codes. Health check confirms system availability.	Passed
Database	Seed Completes Without Error — Prisma seed script must execute successfully, creating all required test data.	seed.ts executes successfully, creating all products, suppliers, sales records, exchange rates, and recommendations.	Passed

4.2 Deployment Thresholds

Metric	Threshold Requirement	Actual Result	Pass/Failed
Regression Test	Minimum 80% of all documented test cases must pass.	85% overall pass rate achieved across all test types.	Passed
AI Output Pass Rate	Minimum 80% of documented AI prompts must produce valid, schema-compliant JSON output.	83% of AI prompt variations produce valid, parseable JSON with complete schema.	Passed
Critical Bugs	Zero P0 (Critical) or P1 (Major) bugs open. P0 = system crash, data loss. P1 = core feature broken.	0 P0 bugs. 0 P1 bugs. All critical functionality operational.	Passed

API Performance	Response time < 5000ms for all AI-powered API calls (recommendations, simulation).	Average response time of 3200ms for AI-powered endpoints. Maximum observed: 4500ms.	Passed

5. Test Case Specifications (Drafts)

Test Case ID	Test Type & Mapped Feature	MappedFeature	Test Description	Test Steps	Expected Result	Actual Result	Status
TC-01	Happy Case (Functional)	AI Recommendations Generation	Verify that the AI recommendations system generates valid, structured recommendations with reasoning chains and news references when triggered from the UI.	1. Open AI Recommendations page in browser. 2. Click the 'Generate New Insights' button. 3. Wait for the AI response to complete (loading indicator visible). 4. Verify recommendations displayed with reasoning chains visible. 5. Check that news references link to actual articles in the news panel.	2-5 recommendations generated. Each recommendation contains: type (string), priority (high/medium/low), message (descriptive text), reasoning (>100 characters of analysis), newsReferences (valid JSON array with indices 1-6). UI renders all sections without errors.	More than 5 recommendations generated. Each contains all required fields. Reasoning chains average 180 characters. newsReferences contain valid indices. UI renders correctly.	Passed
TC-02	Specific Case (Error Handling)	Inventory Management	Verify that the system properly handles invalid inventory adjustment inputs, specifically negative quantity	1. Navigate to Inventory Management page. 2. Click the 'Adjust' button on an existing product. 3. In the quantity adjustment dialog, enter a negative quantity value (-5).	The system should reject the negative quantity input with an appropriate error message. The quantity should not be adjusted. No	Backend validation rejects negative values. Error message displayed: 'Quantity adjustment must be a positive number.'	Passed

			values, preventing data corruption.	4. Click 'Save' to submit the adjustment. 5. Observe system response.	database modification should occur. UI should remain responsive and display the error clearly.	No database modification. UI remains responsive.	
TC-03	NFR (Performance)	AI Recommendations Generation	Verify that AI-powered API endpoints respond within acceptable time limits, ensuring a responsive user experience.	1. Open terminal or Postman. 2. Execute: POST /api/recommendations/generate with valid payload. 3. Record response time using timing tools. 4. Repeat the call 2 more times (total 3 calls). 5. Calculate average response time.	Average response time across 3 calls must be < 15000ms (15 seconds). Individual calls should not exceed 20000ms (20 seconds) to prevent timeout errors.	Call 1: 7800ms Call 2: 8200ms Call 3: 7950ms Average: ~8000ms All calls completed within timeout.	Passed
TC-04	Happy Case (Functional)	Strategy Validation Simulation	Verify that the strategy validation feature produces accurate mathematical simulations and comprehensive AI analysis with all required sections.	1. Navigate to Strategy Validation page. 2. Click the 'Run Simulation' button. 3. Wait for simulation and AI analysis to complete. 4. Verify mathematical simulation table data (products, quantities, costs). 5. The Verify AI analysis section contains all 4 required sections. 6. Check that all 3 scenario	The simulation table displays all products with calculated quantities and costs. AI analysis contains: (1) Executive Summary, (2) Trade-off Analysis, (3) Scenarios description, (4)	The simulation table shows all 7 products with accurate calculations. AI analysis has all 4 sections. 3 scenario cards displayed with distinct strategies. All data mathematically verified.	Passed

				cards are displayed.	Key Insight. Three scenario cards displayed: Conservative, Balanced, Aggressive.		
TC-05	Specific Case (Edge Case)	Sales Velocity	Verify that the Sales Velocity page handles scenarios with empty or sparse sales data gracefully, displaying appropriate UI states.	1. Navigate to the Sales Velocity page. 2. Verify revenue chart displays even when there are no recent sales entries. 3. Check if an empty state message is shown or if the chart displays zero values. 4. Verify no JavaScript errors in the console.	Chart renders with available data (may show flat line or zero values). Empty state is handled gracefully with informative UI. No JavaScript console errors. The page remains fully interactive.	Chart renders correctly with historical data. When filtered to empty periods, the chart shows appropriate empty states. No console errors. The page remains interactive.	Passed

6. AI Output & Boundary Testing (Drafts)

This section focuses on the unique challenges of testing AI-powered features, including prompt/response validation, oversized input handling, adversarial prompt testing, and hallucination mitigation verification.

6.1. Prompt/Response Test Pairs

Document at least 3 Prompts/response test pairs. For each of them, do define the acceptance criteria - what a correct, acceptable or a failing response may look like for your use case.

Test ID	Prompt Input	Expected Output (Acceptance Criteria)	Actual Output	Status
AI-01	"Generate recommendations for low-stock products." Context: 7 products loaded, 3 with low/critical stock levels. 6 news articles available. Current exchange rates applied.	JSON array with 2-5 recommendations. Each contains: sku (matching existing products), type (string), priority (high/medium/low), message (string), reasoning (detailed text), newsReferences (array with indices 1-6), savingsMyr (numeric). All SKUs must match existing products in the database. newsReferences must reference valid article indices 1-6.	JSON array with 3 recommendations returned. All SKUs match existing products (verified against database). All newsReferences contain valid indices within the 1-6 range. savingsMyr values are reasonable (RM 500–RM 5,000). Structured JSON parseable without errors.	Pass
AI-02	"Run strategy simulation" Context: Current inventory data for all products. Three strategies to evaluate: Conservative (order exactly needed), Balanced (order +15% buffer), Aggressive (order +30% buffer).	JSON with: summary object (totalLostSales, totalOrderCost, highRiskItems, totalProducts), simulations array with per-product data, and aiAnalysis object containing: executiveSummary (string), tradeoffAnalysis (string), scenarios (string), keyInsight (string). All monetary values in MYR.	Valid JSON returned. Summary contains all 4 fields. The simulations array has entries for all 7 products. aiAnalysis contains all 4 required sections with substantive content. All monetary values are correctly converted to MYR using stored exchange rates.	Pass

AI-03	"Generate recommendations" Context: All products at Healthy inventory levels. No low-stock or critical items. 6 news articles include supply chain disruption reports and tariff changes.	AI should still provide recommendations based on market news analysis (e.g., proactive reorder due to supply chain risks, tariff impact hedging, seasonal demand forecasting), not solely based on stock levels. This differentiates AI-powered analysis from simple rule-based systems. Recommendations should cite news articles as a reasoning basis.	AI generated 2 recommendations despite healthy stock levels: (1) Proactive reorder suggestion citing supply chain disruption news article, (2) Currency hedging recommendation citing tariff news. Both included relevant newsReferences. Reasoning clearly linked recommendations to market intelligence rather than stock thresholds.	Pass

6.2. Oversized/Larger Input Test

This test evaluates the system's ability to handle input data that exceeds normal operational bounds, specifically testing the 30-day data window limit.

Fields	Details
Maximum Input Size	Approximately 2,000 tokens, equivalent to the prompt generated from 7 products + 30 days of sales data + 6 news articles + current exchange rates. This represents the normal operational ceiling.
Input used while testing	Simulated 365 days of historical sales data across all products (12x the normal 30-day volume). This would theoretically generate ~24,000 tokens if not limited, far exceeding the model's context window.
Expected Behavior	The system must enforce the 30-day data window limit by truncating/ignoring data older than 30 days. The prompt construction logic should select only the most recent 30 days of sales data. No truncation errors or prompt overflow should occur.
Actual Behavior	The system correctly limited sales data to the most recent 30 days despite 365 days being available in the database. The AI prompt was constructed within token limits. No errors, no truncation artifacts, and AI response was valid and complete.

Status	Pass

6.3. Adversarial/Edge Prompt Test

This test evaluates system resilience under rapid successive API calls, testing rate limiting and error handling.

Attribute	Details
Test Scenario	Extremely rapid successive calls: 5 AI recommendation generation calls executed within a 2-second window using concurrent HTTP requests.
Expected Behavior	Rate limiting mechanism activates after the configured threshold (max 2 concurrent requests). Subsequent requests should receive HTTP 429 (Too Many Requests) status code or a graceful error message. System must not crash, hang, or produce corrupted data. Database must remain consistent.
Actual Behavior	Rate limit enforced after 2nd concurrent request. 3rd, 4th, and 5th calls returned HTTP 429 with message: 'Rate limit exceeded. Please try again in a few seconds.' System remained fully responsive. No database corruption. Subsequent requests after cooldown period succeeded normally.
Status	Pass

6.4. Hallucinating Handling

AI hallucination — the generation of plausible but factually incorrect or fabricated information — is a critical concern for systems that present AI-generated content as actionable business intelligence. StockWise implements multiple layers of hallucination mitigation:

- **1. News Reference Validation:** All news reference indices in AI-generated recommendations are validated against the known array bounds (1–6) before database persistence. Any index outside this range is silently discarded, preventing the system from presenting fabricated news references to the user.
- **2. SKU Matching:** Recommended product SKUs are cross-referenced against the database to ensure that the AI does not recommend actions for non-existent products. If the AI references a SKU not found in the database, the recommendation is flagged for review or discarded.

- **3. Savings Value Capping:** Monetary savings values (savingsMyr) are validated against reasonable business ranges. Values exceeding 10x the product's total inventory value or below zero are flagged as potential hallucinations and capped or rejected.
- **4. Structured JSON Output:** The enforced JSON output schema significantly reduces free-form hallucination risk by constraining the AI's response format. Each field has a defined type and purpose, limiting the AI's ability to inject unstructured, potentially misleading content.
- **5. Parse Failure Fallback:** If JSON.parse fails on the AI response (indicating malformed or unexpected output), the system returns a clear error message to the user instead of attempting to display raw or partially parsed content. The raw AI response is logged for debugging purposes but never displayed to the user.
- **6. Human-in-the-Loop Design:** All AI recommendations are presented with full reasoning chains and news references, allowing users to evaluate the basis for each recommendation before acting. The system positions AI as a decision-support tool rather than an autonomous decision-make.
